

Mohammad Parsa Golbou

Network: Browser sends request to DNS resolvers to find the IP address of the URL you typed. Then it sends an HTTP request to the IP address. Server that gets the request is usually a reverse proxy that gives your request to other servers for load balancing and security. At last server sends back information to the Django app.

The URL dispatcher: Once the request from the server enters the Django app, URL dispatcher acts as traffic controller to match the correct view.

View handling: After the correct view was found, view receives the `HttpRequest` which contains all of the details and now it should perform necessary actions based on the logics. At the end it returns an `HttpResponse` object

Template rendering: View collects all the data that is needed and tells the template engine to do the rest. It renders the template by executing template logics and inserting the data. Then it processes results in an HTML file which the view wraps it in an `HttpResponse` object and then it is finally displayed on the screen.
